analysis. 1066 patients with MS from Italy and 721 from France were included. In the multivariate model, anti-CD20 therapies were significantly associated (OR = 2.05, 95%CI = 1.39–3.02, $p < 0.001$) with Covid-19 severity, whereas interferon indicated a decreased risk (OR = 0.42, 95%CI = 0.18–0.99, $p = 0.047$). This pooled-analysis confirms an increased risk of severe Covid-19 in patients on anti-CD20 therapies and supports the protective role of interferon.

Funding Information

This study received no specific funding. French Clinical Research Infrastructure Network for Multiple Sclerosis (FCRIN4MS) is supported by a grant provided by the French State and handled by the "Agence Nationale de la Recherche," within the framework of the "Investments for the Future" program, and by the ARSEP Foundation. Paris Brain Institute (ICM) Clinical Research Infrastructure Network (iCRIN) is supported by a grant provided by the French State and handled by the "Agence Nationale de la Recherche", within the framework of the "Institut Hospitalo-Universitaire" program. The Observatoire Français de la Sclérose en Plaques (OFSEP) is supported by a grant provided by the French State and handled by the "Agence Nationale de la Recherche," within the framework of the "Investments for the Future" program, under the reference ANR-10-COHO-002, by the Eugène Devic EDMUS Foundation against multiple sclerosis and by the ARSEP Foundation.

Introduction

Previous studies have reported data on Covid-19 severity in persons with multiple sclerosis (PwMS) treated with disease-modifying therapies (DMTs). In the Italian study,¹ an increased risk of severe course of Covid-19 was noted in PwMS treated with anti-CD20 therapies and with recent use of methylprednisolone; a slight reduction of risk was observed with interferon use. The French study,² including fewer patients than the Italian study, was not able to detect associations between any DMT and Covid-19 severity, possibly due to lack of statistical power. In the US study,³ an increased risk associated with recent

use of methylprednisolone was confirmed and rituximab was associated with more severe outcomes. Other smaller series have provided mixed results and indications.^{4–5} Moreover, during the first wave of the pandemic, it was not possible to test all symptomatic patients, so the reported cohorts are a mix of suspected and confirmed Covid-19 cases.^{1–3}

Due to the relevance that these results may have for patients' care during the pandemic, it is important to rely on well-established data. Here we present the results of a follow-up collection of data that extends into the "second wave" of the pandemic, pooling results on the effect of risk factors and DMTs on Covid-19 severity using only

confirmed cases from the French and Italian updated cohorts.

Methods

Data of PwMS with suspected or confirmed Covid-19 were retrospectively collected at a national level in Italy and France. Details on data collection and inclusion criteria were previously reported.^{1,2} Only patients with a confirmed Covid-19 diagnosis with a positive test (RT-PCR on nasal and pharyngeal swabs) for SARS-CoV-2 or a positive serological test for anti-SARS COV2 antibodies, and with complete follow-up to death or recovery, were included in this analysis.

All analyses were conducted independently on the two datasets, after harmonizing the baseline variable coding and the definition of Covid-19 severity. Degree of Covid-19 severity was defined by three levels: (1) mild disease not requiring hospitalization nor ventilation; (2) hospitalization or need for ventilation; (3) ICU or death. The association of baseline characteristics and MS therapies with Covid-19 severity was assessed by multivariate ordinal logistic models and pooled by a fixed effect meta-analysis weighted by the inverse of the variance.

The multivariate models were adjusted by age, sex, EDSS, progressive MS course, presence of comorbidities, and recent methylprednisolone use, all variables previously identified as associated with Covid-19 severity.^{1,2} Italian data were also stratified by geographical area. Since EDSS and progressive MS course were highly associated, we ran two multivariate models including EDSS or progressive MS course separately. A heterogeneity analysis was run before deciding how to group DMTs and, excluding Interferon and anti-CD20, the effects of other drugs did not reach a significant level of heterogeneity versus the others (in both datasets). Therefore, we focused this meta-analysis on anti-CD20, Interferon, other drugs, and no therapy (reference category).

Results

Data from 1735 pwMS from Italy and 1031 pwMS from France presenting symptoms of Covid-19 were collected. Of these, 1066 (64%) from Italy and 721 (70%) from France had confirmed Covid-19 and were included in the meta-analysis. Baseline demographic and clinical characteristics of the two cohorts are reported in Table 1. The two cohorts differed for some characteristics: in Italy versus France, there were less females (68% vs. 74%), more obese subjects (12% vs. 8%), and a lower proportion of subjects with secondary progressive MS (SPMS) (9.6% vs. 15.1%). The DMTs distribution was heterogeneous, with a higher proportion of pwMS in Italy versus France

treated with dimethyl-fumarate, natalizumab, interferon, cladribine, and azathioprine and a lower proportion of untreated patients and patients treated with ocrelizumab and rituximab (Table 1).

Table 2 reports cohort characteristics according to DMT and Covid-19 outcomes. Severity outcome was hospitalization/ventilation in 123 Italian patients (11.5%) and in 92 French patients (12.8%), and ICU/death in 27 Italian patients (2.5%) and in 19 French patients (2.7%). Seventeen Italian subjects (1.6%) and 12 French subjects (1.7%) died. In the Italian cohort, 11 pwMS had a progressive disease course, and eight were untreated. In the French cohort, nine subjects were in a progressive disease phase, and eight were untreated.

Age, male sex, EDSS, and comorbidities were all confirmed as risk factors for severe Covid-19 (Figure 1). After adjusting for age, sex, EDSS, comorbidities, and recent methylprednisolone use, treatment with an anti-CD20 agent (ocrelizumab or rituximab) was significantly

DMTs, Disease-modifying therapies; SD, Standard deviation; IQR, Inter-quartile range; MS, Multiple Sclerosis; Methyl-pred, Methylprednisolone.

¹The numbers do not sum up to the total since some patients have multiple outcomes.

associated (OR = 2.05, 95%CI = 1.39–3.02, $p < 0.001$) with an increased risk for severe Covid-19 versus other therapies, whereas the use of interferon was associated with a decreased risk (OR = 0.42, 95%CI = 0.18–0.99, $p = 0.047$). Recent use (<1 month) of methylprednisolone was also associated with a poorer outcome (OR = 2.71, 95%CI = 1.46–5.05, $p < 0.001$). These results were confirmed when including progressive MS instead of EDSS in the model: the OR for anti-CD20 versus other therapies was 2.60 (95%CI = 1.79–3.77, $p < 0.001$), the OR for interferon was 0.38 (95%CI = 0.17–0.85, $p = 0.02$) and the OR for recent use of methylprednisolone was 3.11 (95%CI = 1.72–5.63, $p = 0.001$).

Both in Italy and France, the number of patients on rituximab was low ($n = 20$ in Italy and $n = 34$ in France). However, separating the effect of anti-CD20 agents into rituximab and ocrelizumab, it was possible to detect a higher risk for rituximab (OR_{Italy} = 3.78, OR_{France} = 2.56, pooled OR = 3.04 (95%CI = 1.63, 5.67, $p < 0.001$)) versus other therapies. The effect of ocrelizumab alone was also significant (OR_{Italy} = 1.79, OR_{France} = 1.73, pooled OR = 1.77 (95%CI = 1.15, 2.72, $p < 0.001$)).

We checked for interactions with sex, but we could not find a differential effect of Interferon or anti-CD20 between males and females.

Discussion

Overall, this study reinforces results obtained in smaller series and from the French and Italian cohorts of pwMS: age, male sex, higher EDSS, and presence of comorbidities

are relevant risk factors for severe Covid-19. It also reconciles some apparent incongruities between the two studies on the risks related to DMT use. The increased risk of severe Covid-19 with anti-CD20 therapies and following a recent course of methylprednisolone, detected in the previous Italian study, is confirmed by the present analysis. Furthermore, the decreased risk of severe Covid-19 with interferon therapy, suggested by both previous studies, has also been confirmed.

The comparison of these results to the recently published US study is limited by the large discrepancy in the frequency of severe events reported in the United States and the Italy-France registries. In the confirmed cases, while the rate of hospitalized patients (excluding those admitted to ICU or who died) is very similar (11.5% in the Italian registry and 12.8% in the French registry vs. 13.9% in the US registry³), ICU admission and the mortality rates are not comparable (ICU admission 0.7% and 1.0% in Italy and France vs. 5.6% in the United States; death rate 1.6% and 1.7% in Italy and France vs. 3.6% in the United States). These differences are not justified by the different lethality rates in the general population detected in these countries, that are in the opposite direction, with larger rates in Italy (3.07%) and France (2.09%) vs. the United States (1.82) (<https://coronavirus.jhu.edu/map.html>, accessed on March 27 2021). These differences indicate that caution is needed in comparing Italy and France with results from the United States.

The role of older age, male sex, higher EDSS, and presence of comorbidities detected in this pooled analysis is in line with the US study, as is the impact of steroid use

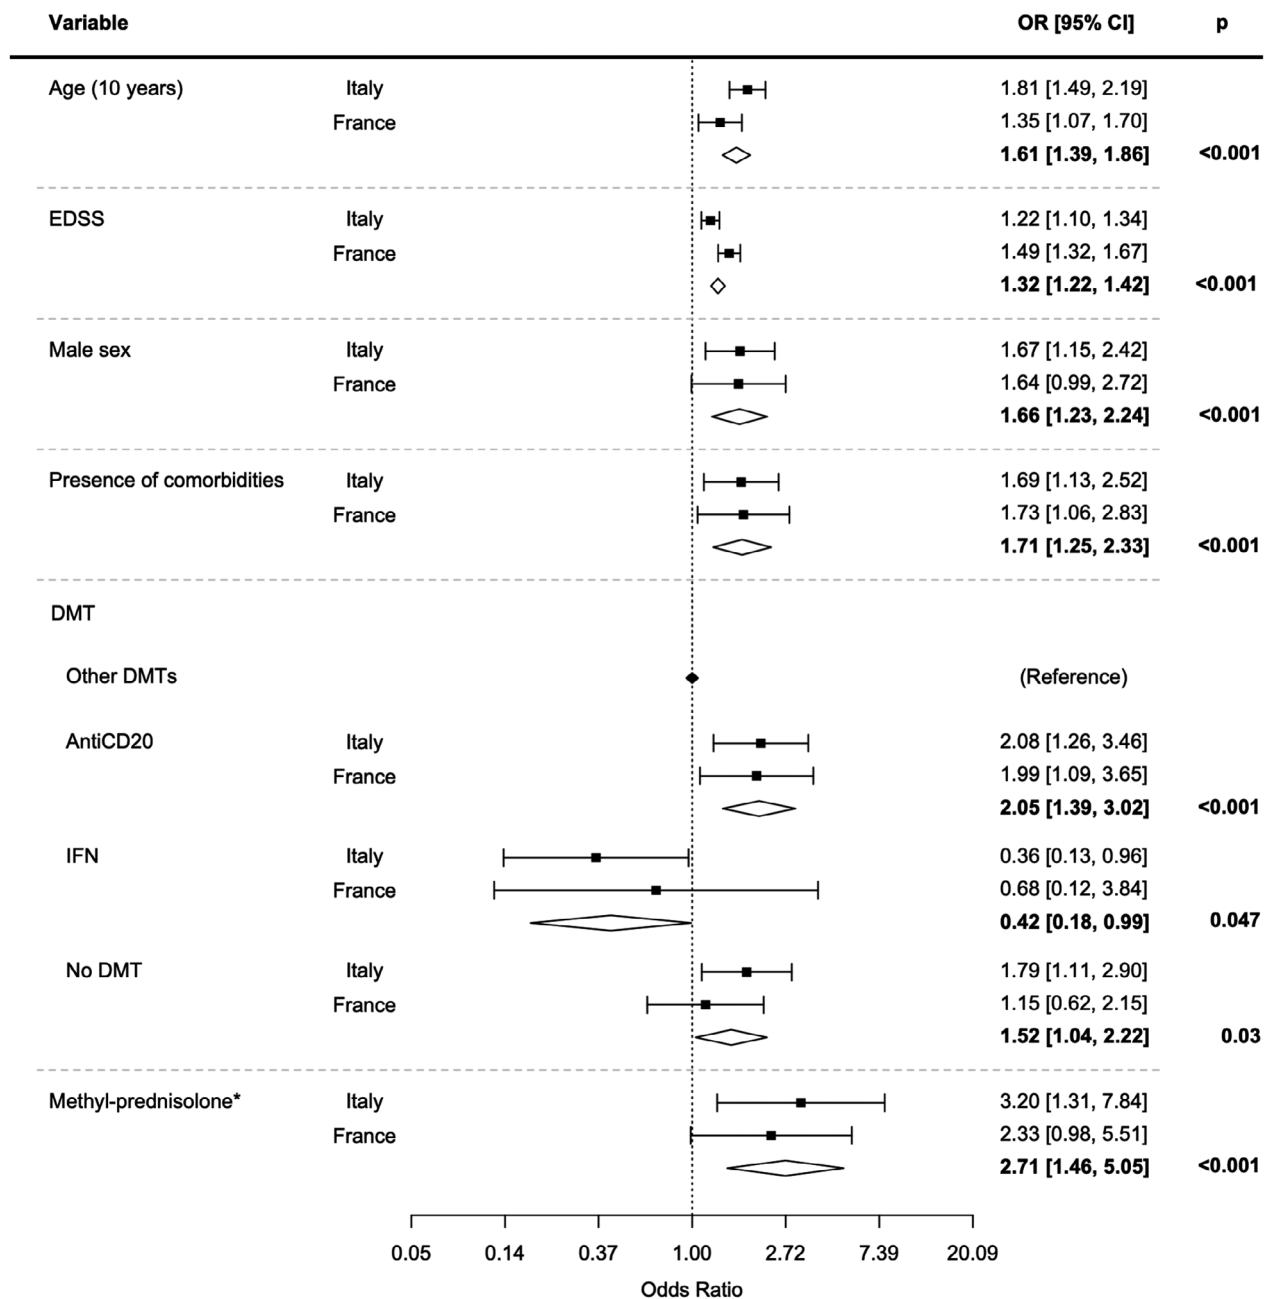

Figure 1. Fixed effect meta-analysis (inverse of variance weighting) including EDSS of multivariate ordinal logistic models investigating the association between Covid-19 severity and PwMS characteristics.

prior to infection. A higher risk for severe Covid-19 associated with anti-CD20 therapies was only detected in rituximab-treated subjects in the US registry. In both Italy and France, the number of patients on rituximab was low, but separating the effect of rituximab from ocrelizumab, a higher risk for rituximab was still detectable, whereas ocrelizumab also had a significant effect. A possible explanation of a higher risk associated with rituximab

is the longer exposure to rituximab therapy, as suggested by the Italian study.¹

With some caveats, the conclusions of this study are in accordance with current knowledge about the biology of Covid-19. Concerning anti-CD20 therapies, a mature B-cell response is important for neutralizing SARS-CoV-2, either by preventing the virus from entering the cell or by lysing infected cells.⁶ Moreover, a larger pool of SARS-

CoV-2-specific, naïve B cells is associated with a better antiviral response.⁷ However, uncertainties remain about the relative impact of B cells on Covid-19 pathophysiology compared to other lymphocyte subsets.⁸ In particular, it is possible that T cells, a robust innate immune response,⁹ or the relative sparing of the IgA response in the mucosal-associated lymphoid tissue,¹⁰ may variably contribute to preventing serious Covid-19 even in the absence of high-titer neutralizing antibodies. This may explain observations where B-cell depletion had limited or no consequences on Covid-19.^{11–12}

The increased risk of severe Covid-19 after recent administration of high-dose methylprednisolone is in line with well-known immunosuppressive effects of corticosteroids. The RECOVERY¹³ trial, demonstrating the efficacy of dexamethasone in hospitalized patients with Covid-19, does not contrast with our results. In fact, the immunosuppressive effects of methylprednisolone given prior to Covid-19 onset plausibly intercept the phase of active viral replication with obvious negative consequences.

Finally, following some conflicting results, the prevailing opinion is now that an impaired type I interferon response correlates with Covid-19 severity. It is therefore plausible that ongoing interferon therapy may offer some protection, at least in subjects with a defective type I interferon response.^{14,15}

Our findings provide a reliable reference for clinical decisions. However, due to the emergence of new viral variants, it will be important to continue monitoring the safety of immunosuppressive therapies.

Acknowledgment

The Musc-19 study group acknowledges Roche for donating the platform for data collection.

Conflicts of Interest

M.P.S. reports a grant from Roche to cover Musc-19 data management; Roche produces ocrelizumab, which is one of the DMTs assessed in this study. The other authors have nothing to report.

Author Contribution

Musc-19 and COVISEP study group participants are listed in Data S1.
